

In today's CC, you need to install MySQL in your system (links are shared in the **Reading Materials** in the portal or you can watch the last half-hour session of the recording).

Next, create a database called **bank** and add three tables into it, namely, **account**, **customer**, **employee**.

You need to identify the fields/column names which will be present in the above mentioned tables along with correct data types for the fields (Try to research online and figure out what fields could be put in).

Next, add sample dummy data to each of the above mentioned tables (2 or 3 records).

**Note:**

- You must only use SQL commands to achieve the above results.
- For your submission, create a .txt file which will have all your SQL queries written in it.

**Marking Scheme**

[Correct SQL commands usage: 10, Appropriate Fields in tables: 5]
